This report represents work of WPI undergraduate students submitted to the faculty as evidence of a degree requirement. WPI routinely publishes these reports on its web site without editorial or peer review. For more information about the projects program at WPI, see http://www.wpi.edu/Academics/Projects.
Abstract

This report documents the design and build process for the Electron Grid of Aligned Documents (EGAD). This framework is an open source project which allows any developer to quickly and efficiently make grid-based applications linking webpages to one another. Modules called widgets can be inserted into any grid cell to implement additional functionality that a developer may want to incorporate into their application. Several commonly-needed widgets are provided, as well as a thoroughly-documented API supporting the development of custom widgets.
Acknowledgements

This paper would not have been possible without the expert guidance of my mentor and close friend, Professor Brian Moriarty. His knowledge of JavaScript ES6, the resources he provided, and his design background were invaluable through the development of this framework. Next, I would like to thank Bill Chamberlain for his guidance when I was learning to program. I would not have pursued an education in computer science were it not for the free-form learning environment of his classroom. The frequent puzzles which illustrated fundamental computer science concepts proved to be exceptionally helpful when furthering my education. Next, I would like to thank Joe Rose for his personal guidance and mentorship throughout my early high school years. Without the persistent guidance of Rachel Palleschi, my writing skills would not have developed to the point where writing a paper of this magnitude was possible. This paper is a direct result of the impact she made on my life. David Medvitz provided me with excellent guidance through the later years of high school. His connection with me allowed me to pursue advance computer science concepts while still in high school, and he heavily encouraged me to attend WPI. Were it not for his advice I would have never have found a field I love as much as this one. Finally, I would like to thank my parents and grandparents. The encouragement from my parents and feedback they have given me through growing up has really shaped me into who I am. They have given me so much support and enabled me to pursue a dream of mine. Without the direct help of my parents and grandparents I would not have been able to attend the schools that shaped me so much, for that opportunity I am incredibly grateful.

Thank you.
Development

Initially, the Electron Grid of Aligned Documents (EGAD) was conceived as an integrated development environment (IDE) for the Perlenspiel game engine. However, it soon became evident that, with the addition of abstraction layers, a more flexible and powerful framework could be created. The project evolved into a generalized tool supporting the creation of applications consisting of an arbitrary grid of web pages, combined with common tools useful to developers when working with Electron.

The inspiration for this project came from Visual Studio Code\(^1\), an Integrated Development Environment made with the Electron framework. EGAD is similar to Visual Studio Code in that it is based on Electron, and allows users to dock and move panels around. EGAD differs from Visual Studio Code in that it assumes nothing about the type of application that is being developed, except that its UI will be grid-based. EGAD handles both the initialization of grid panels and a pipeline for communicating state changes between panels. It can be used to build any Web-based application requiring a flexible panel layout.

Any EGAD panel can be occupied with prebuilt utilities called widgets. EGAD provides a small library of commonly-needed widgets, including a webpage viewer, file browser, code editor, development console, and a tab bar. The framework also documents how custom widgets can be created, giving developers the flexibility to extend EGAD for use in a wide variety of applications. One example would be a tool that allows users to post to multiple social media sites at the same time. This application could have three webpages open at the same time, as well as a

\(^1\) [https://code.visualstudio.com](https://code.visualstudio.com)
text input widget, and a post button widget. When the button was pressed, messages entered into the input widget would be posted to all three social media sites concurrently.

Grid

EGAD’s essential functionality is its ability to create and manipulate a grid of functional application modules. The grid is made up of horizontally resizable columns, each containing child rows that can be individually resized vertically. Locations in the grid are referred to as cells. For example, the grid presented in Figure 1 is comprised of five columns, each containing five rows. EGAD’s API function grid.getWidget(column, row) can be called to reference a specific cell in the grid. This returns the widget stored in cell (column, row). If there is no widget at the location specified, the value null is returned. Similarly, the grid.setWidget(column, row, widget) function can be used to set or replace the widget residing in a grid cell.

The grid.addWidget(column, row, widget) function is used to add an entirely new cell to the grid at the specified location. This allows for grids to have independently-formatted rows or columns. Figure 2 depicts a grid with one cell in column one, and three cells in column two. Structuring rows in this free-form manner enables a variety of application designs, thus increasing the use case flexibility of the EGAD framework.
The network of white bars distinguishing cell boundaries in the grid are referred to as **drags**. All cells in the grid detect what drags represent their boundaries, and can be resized dynamically when any of these drags are moved. To move a drag, a user simply clicks on the white boundary and drags it to a desired location. All the drags that move horizontally span the entire height of the window. This ensures that all cells within a column will have a consistent size. Rows are not consistent throughout the grid. Every column can contain an arbitrary number of rows. The only guarantee about a column is that it will have at least one row. Figure 3 illustrates how moving a drag horizontally will resize all cells in a column, however resizing a drag vertically will only change the size of cells in that column.

![Figure 3. Demonstration of horizontal and vertical resizing.](image)

Every cell in the grid can contain a single **widget**. Widgets are containers for displaying and manipulating data. When a grid is initialized, an array of widgets is specified. These widgets are synchronously initialized, which means that the second widget will not be initialized until the first widget is done initializing. The parent widget class is abstract; therefore, independent developers can design their own widgets to add functionality needed for specific applications.

EGAD offers a library of built in widgets which provide commonly-needed functionality, allowing developers to quickly start developing an application. Figure 4 shows a 5x5 grid initialized with three instances of the built-in file tree widget. Each of these instances are completely independent. They can point to different file locations on the disk, have different
stylistic themes, and can configure properties of their specific file tree without affecting the appearance or functionality of other widgets.

The number of cells in a given column is not fixed. At any time, an EGAD application can modify how many cells there are in a column by calling the `grid.addWidget()` function. Widgets can be removed from the grid by calling `grid.removeWidget()`. These functions allow the layout of an application to be modified at any time. A possible use case for this functionality is to show a tooltip widget when the user is interacting with a certain piece of data. When the tooltip is no longer needed, the widget can be removed.
Save System

Whenever an application built with EGAD is closed, a custom save object is generated representing the exact state of the grid. To achieve this preservation of the grid state, all columns are iterated through and their widths are recorded. Then the height of each cell in each column is recorded. This forms a two-dimensional array of width and height data that can be used to recreate the dimensions of the grid when re-opened.

Cells containing widgets need to have a way to persist data as well. The parent widget class has an abstract `Save` function that is overridden by child widget classes. The implementations of this method in child classes return JSON objects containing all persistent data needed for that specific widget. For example, the file tree widget generates a custom save object with a “path” attribute which keeps track of the directory to which the file tree is pointing. These custom JSON objects are inserted into the object containing the width and height data of the associated cell. This JSON object is then written to a configuration file specified by the developer. When the application is re-opened, the save file is loaded, and the JSON data inside is parsed back into a save object. As the grid is initialized, each widget reads its relative save information from the save object to return to the state existing when the application was closed.

If additional save information is needed, the developer can integrate with the `fileManager` class, to read and write files. This class acts as a wrapper for the default node.js file system module `fs`, and enables a developer to easily read, write and manage external files and integrate them with their application.

---

Widget

Widgets are the fundamental display container used by EGAD. The parent widget class is an abstract class which defines many useful helper functions and data management tools. This parent class also defines many fields that every widget needs to support.

Widgets must contain a name describing itself, a column (x), and a row (y) position to be directly parented to in the grid, and a reference to a DOM element that the widget can internally modify. This DOM element is what is inserted into the application when a widget is parent to an (x, y) cell. Widgets also maintain a list of references to other widgets with which they may need to exchange data. This is how widgets communicate between one another.

Widgets also generate a JSON object, and store any configuration data they need inside that object as attributes. All configuration data that a widget needs when it is initialized is read from this object, which EGAD saves the object’s state when the application is closed.

The final field that every widget has is an isLoaded Boolean that returns true once a widget has successfully been initialized. This field is used when widgets want to communicate between one another. If the widget that is trying to be accessed isLoaded is false, there is no guarantee that any field within that widget will be defined. If isLoaded is true, then the widgets constructor has been called, insuring that all fields on the widget are initialized and safe to reference.

In order for widgets to rely on one another, it is paramount that the initialization order of all widgets can be controlled. If widget A relies on widget B, and widget A’s constructor references fields in widget B, if widget B has not finished initializing, some or all of its fields may be undefined. One would think that this solution could be solved by simply assuring that
widget \( B \) will have been initialized by widget \( A \)’s constructor. However, it is not that simple. Assume that we create widget \( B \) immediately before widget \( A \) as is seen in Figure 5.

```javascript
let widgetB = new Widget({name:"File Tree", col:0, row:0}, {});
let widgetA = new Widget({name:"File Tab Manager", col:1, row:1}, {widgetB});
```

*Figure 3. Importance of initialization order.*

Widget \( B \) could spawn asynchronous processes in its constructor. This would cause widget \( B \) to be in a state where its constructor has terminated yet not be fully initialized. Since its constructor has terminated, the next line of the program would execute to create widget \( A \). If widget \( A \) goes on to reference widget \( B \) in its own constructor, there is no guarantee that the fields being accessed will be defined. Now widget \( A \) has finished executing its constructor with references to undefined in places that should reference fields of widget \( B \). By this time the asynchronous calls made by widget \( B \) have finished executing, and widget \( B \) updates its DOM element to use the data retrieved from the asynchronous calls. This will put the grid in a state where widget \( B \) looks as if it were initialized first, however widget \( A \) really finished initializing first, and contains references to invalid data taken from widget \( B \).

The solution to this problem is to assert that any widget created must return a promise from its initialization call. Any asynchronous calls made within this constructor must be handled in such a way that the promise does not resolve until all asynchronous calls have terminated. With these rules in place, an array of widgets can be initialized within a locking loop, as illustrated in Figure 6.
This loop uses a new feature of JavaScript ES6, `async await`\(^3\). The keyword `async` can preface any function within JavaScript. This keyword asserts that within the body of the function some asynchronous function will be executed. This keyword also enables the use of a second keyword, `await`. The keyword `await` must preface an asynchronous function call. When the code in Figure 6 on line 513 is interpreted, the execution of line 514 will halt until the asynchronous call spawned from line 513 terminates. The code being executed on line 513 is evaluating the promise returned from a widget’s `initialize` function. This promise was designed to not return until all asynchronous calls in a widget’s `initialize` function have terminated. Therefore, Figure 6 depicts a blocking chain that will wait to initialize the next widget in the chain until the previous link has finished initializing. This design ensures that widget \(B\) will be initialized by the time it is passed to widget \(A\).

One of the design goals for widgets was for them to encapsulate all of their functionality within their class. The reason for this is that it enables any widget developed for an EGAD application to be deployed in any other EGAD project. In the future, users will be able to search the web for an EGAD widget that they would like to include in their project, and hopefully find one that works as-is, or which can edited to fit their needs. The open-source EGAD project will

---

3 https://www.ecma-international.org/ecma-262/8.0/#sec-async-function-definitions
allow users to develop applications quickly through open-source widgets developed by other community members.

EGAD’s library of pre-defined widgets are intended to help developers implement common functionality quickly, and to demonstrate how flexible widgets can be. The included widgets are a webpage viewer, a file browser, a code editor, a tab bar, and a console. These widgets are especially useful for developing Integrated Development Environments. Initially this project was targeted at making IDE’s, however with changes like the abstract widget class, many more applications can be developed with this framework. Rather than making an exhaustive set of widgets for all possible applications, the abstract widget structure was created to allow developers to build their own new widgets easily.

Figure 7 depicts a custom widget built for the EGAD framework. The application that this custom widget was developed to allow users to manipulate models in 3D space. A helpful tool for this kind of manipulation is a transform viewer that displays the rotation and scale of a 3D model. The widget depicted in Figure 7 uses three sliders and an array of text cells to show the transform of the 3D model’s current position in space. The widget can be placed into any cell and will automatically display itself. The widget also records its current sliders values inside of its save object. This preserves the state of all sliders between the application closing and opening. This widget was quickly implemented, relying heavily on the built-in properties of widgets to manage persistent data and display the widget on the screen.

![Custom transform widget.](image)
**Webview**

The goal behind the Webview widget is to wrap the Electron Webview\(^4\) DOM element within an EGAD widget. Webviews act as more powerful IFrames, in that they allow a developer to tap into the output stream of a webpage. Webviews also provide access to a V8\(^5\) instance interpreting any JavaScript in the webpage. The ability to access these streams is wrapped to internal functions that allow a developer to execute a callback whenever data is written to the page’s output. Other calls exist to run JavaScript within the Webview. This provides developers with immense power and control over the pages that they display within Webview widgets. Developers can use JavaScript to interact with all aspects of the webpage and listen to responses from the webpage through the output stream.

Developers can embed any webpage into their application by simply specifying the URL of the desired page. The URL can either point to an external webpage hosted on the Internet, or it can specify a local path to an .html file. The ability to communicate directly with these web allows developers to have web pages interact with one another. Figure 8 depicts a 3x3 grid with four Webviews inside of it. The centermost Webview is pointing to an HTML file included in the project, where the other three Webviews are pointing to popular social media sites.

![Figure 5. 3 x 3 grid of Webviews.](https://electronjs.org/docs/api/webview-tag)

\(^4\) [https://electronjs.org/docs/api/webview-tag](https://electronjs.org/docs/api/webview-tag)

\(^5\) [https://v8.dev](https://v8.dev)
File Tree

One feature which many projects rely on is the ability to traverse a file structure. To implement this within EGAD, the FancyTree\(^6\) library was selected and wrapped within a widget. This library requires the developer to pass a JSON object representing a file directory structure to the fancy tree class constructor. In order to generate this JSON object, the node.js file system module is used. This module allows a computer’s local storage to be accessed through JavaScript using EGAD’s `getProjectFiles()` function, which allows a user to access all files and subdirectories within a specific directory. This method also utilizes an ignore object to omit certain files from the JSON object returned. Much like a `.gitignore`\(^7\), this object is a blacklist of files to exclude from the returned object. If the developer wanted to ignore all .html files in all directories, they would use the wildcard `*` character. This would appear as `*.html` inside of their ignore object. If only a specific file should be ignored, it can be excluded by simply typing its name (such as “index.html”) inside the ignore object. If all files of a specific name with different file extensions should be ignored, the wildcard character can be used. The following would ignore all files named example with any file extension: “example.*”.

Figure 9 depicts the output of the `getProjectFiles()` method, and shows the resulting File Tree widget that is generated from this data. The desired outcome of this widget is to allow the developer to simply specify a directory that they want the user to have access to, and have this directory and all sub directories represented visually in an interactable tree. Much like the Webview widget, the File Browser widget requires an additional URL parameter to be passed in through the widgets `configData` object. This URL can point to any location on the host computer.

\(^6\) [https://github.com/mar10/fancytree/wiki](https://github.com/mar10/fancytree/wiki)
\(^7\) [https://git-scm.com/docs/gitignore](https://git-scm.com/docs/gitignore)
In future versions of EGAD, this module will be improved to support remote file server access through the FTP\textsuperscript{8} protocol. This will enable far more complex applications by allowing developers to create an FTP widget which could connect to a remotely-hosted server or database and display the resulting files in a tree structure.

\textsuperscript{8} \url{https://tools.ietf.org/html/rfc959}
**Code Editor**

The Code Editor widget is a language-agnostic editor which allows a user to edit any programming language specified by the developer. This widget also contains a custom Language Parser which suggests commands that a user could be trying to type. Code Mirror\(^9\) is the base editor tool that the widget is designed and built around. Code Mirror is open source, widely used, incredibly flexible, and well-documented making it an excellent choice for a language-agnostic editor. The widget takes in an additional parameter called `languageMap` which associates file extensions with languages. This widget has configurable hotkeys for saving the code being edited to a file, as well as facilities for copying, pasting, and commenting code, and registering function callbacks to be executed whenever a hotkey is triggered.

The language parser works by loading a JSON object which describes the language. Information such as variable keywords, scope declaration characters, comment headers and footer as well as any function names are included in this object. When a file is loaded, the file extension is checked against a map of known associations stored within the Code Editor widget. For example, if a file was opened with the extension `.js`, the JavaScript configuration file would be loaded. Then all scopes within the file are detected and a tree structure is generated. This tree has information about the line start and end of every scope in the file. This information allows the Language Parser to know exact which scope any line of the file is within. Additionally, whenever a new line is added or removed from the file, all scopes below that point are offset such that the line start and end values of all scopes in the tree hold true throughout editing the file. After all scopes have been established, the file is iterated through line by line and broken up

\(^9\) [https://codemirror.net](https://codemirror.net)
into smaller tokens. These tokens are compared to the list of known variable keywords to try and determine what the user is trying to type. When variables are created, they are inserted into the scope that the cursor currently. Figure 10 shows an example of a JavaScript file with scopes and variables highlighted. Whenever a new character is added to the file, the changed line is tokenized. The last token is compared to all known functions that exist in the language, as well as any variables that are accessible in that scope. The parser then generates a set of predictions as to what variable or function names the user could be trying to type. The user can then confirm one of the suggestions to autocomplete what they were typing without typing the entire expression.

A real-world use case for this “IntelliSense” functionality is suggesting library functions for the Perlenspiel game engine. In Figure 10, the IntelliSense being displayed is referencing a JSON object listing all library functions of Perlenspiel. This presents programmers with possible functions that they could be trying to reference and inserts the exact spelling of the library functions into the code editor.

Figure 7. Example of Code Editor widget.
Development Console

The Console widget acts as a wrapper to interface with standard input and output streams. This widget was developed to integrate with Webview widgets or processes spawned from EGAD. Figure 11 depicts the output of a Webview widget wrapped to an instance of the development console widget. Whenever the Webview writes to its output stream through a JavaScript call to console.log, the stream text is also passed into the development console widget. The development console widget simply wraps this output to its own output text area.

The development console also has an input text field. The arrows in Figure 11 depict a command being sent to the stdin stream of the WebView. The command that is being interpreted tells the Webview to write “Test” to its console. This write to console is then sent to the Webview’s output stream which causes “Test” to show up in the Development Console output area.

Developers are also able to link Development Console widgets to other processes spawned by EGAD. Whenever EGAD spawns a process, references to the input and output streams of that process are stored for later use. These streams can easily be mapped to a Development Console to view the print statements generated from a running process.
Tab Bar

The Tab Bar widget allows a user to switch between multiple files open at the same time. This widget requires a reference to a File Browser widget. The Tab Bar widget listens for the file tree to signal that a file has been double clicked on. When this event is sensed, the file that was clicked on is passed to the Tab Bar widget, which looks at the file extension and executes the callback function registered for that type of file. It is the developer’s responsibility to provide callback functionality for every file type that they want the ability to open. Figure 12 shows the result of a callback function which adds an image div to the DOM when a “.png” file is clicked. Whenever a new file is clicked on, the Tab Bar will create a new tab for that specific file. These tabs can be clicked on to run the callback function for that file.

Currently, EGAD tabs are not able to be closed or moved around. This limited functionality is due to the time invested in this project so far. The Tab Bar widget was not a priority for the sample applications being developed, so only basic functionality has been integrated so far. In future versions of EGAD, polishing up the visuals of the tab bar and enabling users to drag tabs around will be priority features.
Canvas

The Canvas widget was designed to provide an easy way for developers to integrate with WebGL\(^\text{10}\). WebGL is a web implementation of the Open Graphics Library (OpenGL)\(^\text{11}\) which provides hardware acceleration for graphics applications on web pages. Since each cell of the EGAD grid is its own web page, WebGL can be used to provide a hardware-accelerated canvas to the developer. WebGL canvases are often used as the basis for HTML5 games. If a developer were to make a game engine based off the EGAD framework, a cell could be populated with a WebGL canvas and other cells could be used for debug information and world editing utilities. Also, since EGAD is written on top of Electron, the project can be compiled to native executables and distributed across systems easily.

The Canvas widget itself preserves no information between runs of the application, and simply acts as a display which other JavaScript files can subscribe to. If a developer writes a piece of code to integrate with WebGL, such as a render function that draws an element, they can send this element to the canvas by calling `canvas.subscribeToDraw(<drawFunction>)`. This function adds the specified function to an array of callbacks to be executed whenever the canvas redraws. This way developers can add draw functionality to the canvas class without modifying the canvasWidget class itself. These callback functions are executed at a fixed interval; EGAD assumes that the fastest the canvas can be refreshed is 255 times per second. Every additional draw call added to this function increases the total time it takes to render a frame of the game, possibly decreasing the overall performance. Since most games target 60 fps, there is a lot of leeway for adding additional draw calls. If a developer wants to set the canvas to render at a

\(^{10}\) [https://www.khronos.org/webgl/](https://www.khronos.org/webgl/)

\(^{11}\) [https://www.khronos.org/opengl/](https://www.khronos.org/opengl/)
fixed frame rate, they can simply call `canvas.setFrameRate(int frames)` to limit the refresh rate to ‘frames’ per second.

Figure 10. Blank WebGL canvas.

Figure 13 depicts a blank Canvas widget adjacent to a Transform widget. There is nothing displayed in the canvas window, because WebGL implementation is the application developer’s responsibility. There are many ways to implement a WebGL renderer, rather than one best way to implement things. Libraries such as pixi.js and three.js\(^\text{12}\) provide excellent implementations of many commonly desired WebGL use cases. The canvas being blank allows it to easily be used as a render target for libraries such as three.js.

Process Spawner

One of the most powerful features of node.js\(^{13}\) is its ability to start a native process and capture the streams going into and out of that process. EGAD encapsulates this functionality inside a utility class called `processSpawner`. This class allows the developer to spawn native processes and pass callback functions to the input and output streams of those processes. Any time stdin detects input, it will trigger the callback function passed into the processSpawner and forward the input data to the callback function. Similarly, any time stdout detects that data has been written, the callback function for stdout will be triggered with the output data passed to the function. The processSpawner class also allows a developer to register interest in a process terminating through an additional callback function. This function is triggered whenever the spawned process terminates, and the exit code of the process is forwarded to the `onClose` callback function.

Figure 14 shows the output stream of a spawned process being mapped to the V8 developer console. The spawned process is a game engine which sends all of its logging data to standard out. These prints are caught and logged to the console. The console also has an input field where a user can type. Anything that is typed into this input field is sent to the game engine. The game engine sends the text from this input stream directly into its scripting engine and assumes that the sent code is valid JavaScript. The engine will then interpret the script and compute the result. This is useful for debugging and gives developers access to variables inside the game engine at runtime.

\(^{13}\) [https://nodejs.org/en/](https://nodejs.org/en/)
One possible application for the processSpawner is to compile and then run code written inside a Code Editor widget. Another possible application for the processSpawner is to run test cases on a running program. If internal variables of the process can be queried through stdin, and then printed to stdout, a simple automation test application could be written to check that objects are in certain states at certain times. This would allow users to create automated test cases, and regression tests to help maintain functionality in an application throughout the development lifecycle. Developers would even be able to detect the program closing prematurely by registering a callback function when the process terminates. They would then be able to compare the exit code of the process against a known return value to ensure that the process ran to completion.
Development Customizable Menu System

Applications have drastically different menu layouts. In order to support as many layout options as possible, nothing can be assumed about the menu requirements for an application. If a Fullscreen application or game were to be developed a menu may not be wanted at all. In a photo editing application, there could be extensive menus. All customization and callback functions need to be pushed onto the developer’s hands. In EGAD, this is implemented through a straightforward interface which allows the developer to map callback functions to hotkey commands. This mapping can then be parented to a menu tab the developer creates such as “file” or “edit” or “preferences”. This menu functionality is encapsulated within a helper class. New menu tabs can be defined by simply calling the function

```javascript
menuBuilder.addMenuDropDown(<name>);
```

This function will create a new tab called ‘name’ to the menu. To add functions to tabs, a developer simply needs to call

```javascript
menuBuilder.registerFunctionCallback(<tab>, <name>, <key>, <function>);
```

This function adds a new option to <tab> with the name <name>. For instance, a developer may add the ‘save’ option to the ‘file’ tab. <key> indicates the hot key which triggers this menu option. In the case of ‘save’ this key would most likely be ‘S’ so when ‘ctrl + S’ is pressed the ‘save’ function will be called. The <function> parameter is the string name of a function within editor.js to execute when this menu item is triggered. Figure 15 shows a menu next to the code required to build that menu.

```
function(menu, function, key, name, tab) {
    let file_dd = menu.addMenuDropDown("File");
    menu.registerAppCallback(file_dd, 'Quit', 'Q', 'quit');
    menu.registerFunctionCallback(file_dd, 'Save', 'S', 'save');
    menu.registerFunctionCallback(file_dd, 'New', '=', 'newWidget');
    menu.registerFunctionCallback(file_dd, 'Remove', '-', 'removeWidget');
    menu.registerWindowCallback(file_dd, 'Developer Console', 'I', 'toggleDevTools');
    let help_dd = menu.addMenuDropDown("Help");
    let test_dd = menu.addMenuDropDown("Test");
    let project_dd = menu.addMenuDropDown("Project");
```
Real world Applications

To accompany the release of EGAD Version 1.0, three example applications were developed to provide a starting point for different kinds of applications. The first project that was developed was a language-specific Integrated Development Environment called the Perlenspiel IDE. Perlenspiel is the custom library that this IDE was developed to edit. The language file that Perlenspiel uses is included and well documented, so users can adapt this application to fit their language-specific needs.

The second application which was developed is a tool that spawns a process and then maps the input and output streams of this process to the V8 developer console. The purpose of this application is to show users how easily native processes can be manipulated through this framework. This application could be modified to fit a wide variety of needs. The final application that was developed is a 3D Model viewer which uses an OpenGL enabled Canvas widget, as well as a custom Transform widget. This application allows users to view 3D .ply files and modify their transforms in space. The reason this application was developed is to show users how simple it is to create new widgets for the EGAD framework. The Transform widget is a well-documented custom widget that will work in any EGAD project. These three applications serve as jumping-off points for users who want to develop their own applications in EGAD.
Perlenspiel IDE

Professor Brian Moriarty developed the Perlenspiel game engine for use in his digital game design courses at WPI. In these courses, students use JetBrains WebStorm\(^{14}\) to develop web games in Perlenspiel. WebStorm is an integrated development environment that focuses on developing websites. This tool works very well for developing Perlenspiel games; however, there are several missing features that would allow students to develop Perlenspiel games faster. A tool with features such as, the ability to view the output game in real time, IntelliSense recognizing and suggesting Perlenspiel library functions, and the ability to view and change variable values in real time, would allow students to debug their games in new visual ways not possible with traditional WebStorm.

EGAD would be an excellent choice for developing the application described above. The editor itself would be comprised of a grid utilizing many of EGAD’s built-in widgets. The grid would be comprised of three columns. The left column would contain a file tree, and a custom documentation widget. The center column would contain a Tab Bar widget, a Code Editor widget with a custom language file, and a Console widget. The right column would contain a Webview widget pointing to the Perlenspiel game being developed as well as a Webview widget displaying the documentation for Perlenspiel. This design provides exactly enough functionality for Perlenspiel specifically and only requires the development of one custom widget.

\(^{14}\) [https://www.jetbrains.com/webstorm/](https://www.jetbrains.com/webstorm/)
Figure 16 shows version 1.0 of the Perlenspiel IDE Application. Whenever code is typed in the code editor, the language interpreter generates IntelliSense suggestions which appear in the leftmost column. Every time code is saved, the live output is updated. Any console logs from the live output are wrapped to the output stream. Code can be injected to the live output through the input field under the output stream. This input field is evaluated by the live output’s V8 instance, which allows for any variable to be changed in real time.

This application allows for easier development and testing of games made with the Perlenspiel game engine. Rather than saving a Perlenspiel webpage and replaying the game to the state where changes have been made, developers can evaluate and change the values of variables throughout the development process in real time.
FraudTek IDE

The FraudTek game engine is written with a Java backend which interprets JavaScript game code at runtime. The engine loads a custom library into its JavaScript interpreter in order to register many additional commands and primitive types. These additions are unique to FraudTek and unknown to all JavaScript IDE’s IntelliSense. This makes it difficult to write FraudTek scripts because spelling errors and referencing unknown library calls are not caught by a traditional IDE. The editor simply does not know if a reference is spelled correctly or not because it has no knowledge of these library specific references. Another problem with script creation in traditional IDE’s is that there is no way to directly execute the FraudTek script interpreter to test the newly created scripts. The script interpreter is a java executable that wraps errors to stdout and allows running scripts to be modified in real time through stdin.

The EGAD framework would allow a developer to easily create a IDE to program FraudTek scripts. A 2x2 grid could be created containing a FileTree widget, a custom IntelliSense widget, a Code Editor widget, and a Console widget. The FileTree would point to the active FraudTek project directory. All custom language functions would be added to a custom language file which integrate with the custom IntelliSense widget to provide suggestions about the FraudTek Script that is currently being written. The Code Editor widget would be formatted as if it were plain JavaScript, however, have knowledge of the custom FraudTek Functions through the custom language file. The Console widget would be wrapped to an instance of FraudTek spawned through the process spawner. Overall this application could be created with minimal custom development and provide an incredibly more intuitive editing experience when creating FraudTek files.
Figure 17 depicts the FraudTek Editor. A File Tree shows all files in the project in the top left corner. Below that, an IntelliSense shows all possible functions that can be called from the current line the cursor is on inside of the Editor. The Editor shows a script file which can be edited and interpreted at any time. Below the Editor a Console widget allows the developer to query a running instance of FraudTek to monitor variables or modify a running script. The Right column is the V8 output console. This output is wrapped to the FraudTek process returned from the process spawner and is updated whenever a new instance of FraudTek is run. Overall this application took little time to build and provides immense utility to a FraudTek developer.
3D Viewer

The 3D viewer is an application to demonstrate the 3D performance capabilities of the EGAD library. The application uses a Canvas widget and a Transform widget to allow the user to modify the rotation of a model in 3D space. Figure 18 shows a WebGL enabled canvas on the left and a Transform widget on the right. The canvas widget can interact with the WebGL canvas to modify the rotation of various objects in the scene. In the future, this application will be further developed into a 3D game engine, where users can click on elements on the WebGL canvas and see that entities properties in the right panel.

*Figure 15 | WebGL enabled Canvas with Transform*
GitHub

EGAD is an open source framework available on GitHub which includes everything needed for a developer to get started. Anyone can view the entire source of the EGAD Framework directly on GitHub or fork the repository to make their own improvements. If a drastic oversight was made while developing the framework, anyone can come up with a fix and submit a pull request to have their change added to the official EGAD repository. The documentation for EGAD is also included in the repository to encourage developers to learn how to use the built-in functionality of EGAD, as well as extend that functionality. The project can simply be cloned to a developer’s computer. This project is open source to facilitate adoption and encourage adaptation.

The repository can be viewed at https://github.com/bhsostek/EGAD

Grid

Creates a new Grid, this contains columns, rows, and drag elements. Columns are vertical and can have n rows inside them. Rows are containers for divs, as the rows are resized, the div content will also be resized to fit.

Constructor

```
new Grid(width, height, columns, rows)
```

Source: grid/grid.js, line 35

The Grid class takes in the window width and height, passed in to establish a basic window size. The default grid has no rows or columns within it. To add content call the Grid#createColumn method.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>Number</td>
<td>This is the width of the grid in pixels.</td>
</tr>
<tr>
<td>height</td>
<td>Number</td>
<td>This is the height of the grid in pixels.</td>
</tr>
<tr>
<td>columns</td>
<td>Number</td>
<td>This is the number of columns that the grid should be initialized with.</td>
</tr>
<tr>
<td>rows</td>
<td>Number</td>
<td>This is the number of rows that each column should have.</td>
</tr>
</tbody>
</table>

Methods

```
addColumn(column)
```

Source: grid/grid.js, line 362

This method can be called to add a column to the current grid. The grid is flexible, and has a constants size of 100%, when a new column is added, the default width of the column is \((1/n)\)% where n is the number of columns in the grid. This method can be called at any time to add a new column.

Parameters:
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>Column</td>
<td>The Column that will be added.</td>
</tr>
</tbody>
</table>

**addDrag(drag)**

Source:  grid/grid.js, line 392

This method lets the user register a new drag to appear on the window.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>drag</td>
<td>H_Drag</td>
<td>The Horizontal drag to add to the window.</td>
</tr>
</tbody>
</table>

**addWidget(widget)**

Source:  grid/grid.js, line 707

This function adds a widget into the grid of widgets being displayed

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>Widget</td>
<td>This widget will be added into the grid at widget.col widget.row</td>
</tr>
</tbody>
</table>

**createColumn(elements, properties) → {Column}**

Source:  grid/grid.js, line 133

Creates a Column. A column is a resizable container for data. Columns contain an index (left to right) starting at 0, representing which column they are numerically on the screen. Columns also contain a list of children

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>elements</td>
<td>Array</td>
<td>This is an array or a single html element. For every dom element passed, a new unique row will be created in this column</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>----------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>properties</td>
<td>Object</td>
<td>These are additional configuration parameters that can be passed into a column.</td>
</tr>
</tbody>
</table>

**Properties**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>String</td>
<td>A hexadecimal color to apply to the background of this column.</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>A string representing the ID that should be associated with this column.</td>
</tr>
</tbody>
</table>

Returns:

A json object representing a Column.

**createDrag** *(col1, col2) → {H_Drag}*

Source: grid/grid.js, line 288

Creates a horizontal Drag. A horizontal drag is a small element conjoining two Columns. Clicking and dragging on a Drag will change the relative scale of the linked columns.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>col1</td>
<td>Column</td>
<td>The first column</td>
</tr>
<tr>
<td>col2</td>
<td>Column</td>
<td>The second column</td>
</tr>
</tbody>
</table>

Returns:

Returns a json object representing a horizontal drag.

**createVDrag** *(row1, row2) → {V_Drag}*

Source: grid/grid.js, line 330

Creates a vertical Drag. A vertical drag is a small element conjoining two rows. Clicking and dragging on a vertical Drag will change the relative scale of the linked rows.

**Parameters:**
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row1</td>
<td>Element</td>
<td></td>
</tr>
<tr>
<td>row2</td>
<td>Element</td>
<td></td>
</tr>
</tbody>
</table>

**Returns:**

Returns a json object representing a Column.

**Type**  
V_Drag

### executeCallbacks()

**Source:** grid/grid.js, line 468

This function executes all registered callback functions inside of this grid.

### generateSaveObject() → {Object}

**Source:** grid/grid.js, line 536

This method is called when the editor is saving the active configuration. All columns and rows report their widths and heights respectively. A multi-dimensional array object is constructed. This array has all of the height data needed to recreate the current editor spacing on the next editor load.

**Returns:**

sizes - The widths and heights of the current window configuration.

**Type**  
Object

### getCOLUMNS() → {Array.<Column>}

**Source:** grid/grid.js, line 585

Get all columns in this grid.

**Returns:**

COLUMNS - The columns that make up this grid.

**Type**  
Array.<Column>

### getHEIGHT() → {Integer}

**Source:** grid/grid.js, line 577

Get the grid height.

**Returns:**
HEIGHT - The height of the window.

Type  Integer

getWidget(col, row) → {Widget | null}

Source: grid/grid.js, line 678

This function returns the widget stored in grid cell (col, row). If there is no widget in that cell null is returned.

Parameters:

Name | Type | Description
--- | --- | ---
col | Integer | This the column or X of the grid that you are trying to access.
row | Integer | This the row or Y of the grid that you are trying to access.

Returns:

widget - This is the widget in grid cell (col, row) if there is no widget in that cell, null is returned.

Type  Widget | null

getWIDTH() → {Integer}

Source: grid/grid.js, line 569

Get the grid width.

Returns:

WIDTH - The width of the window.

Type  Integer

init(widgets)

Source: grid/grid.js, line 667

Initializes the grid with Widgets. A Widget is a synchronously spawned promise. This function will iterate through the widgets array and initialize one widget after another. This way later widgets can have earlier widgets passed into them. Example [Document(requires:[]), Tab(requires:[Document])] In this example the Widget Document requires nothing and is the first widget to be initialized in the program. Tab is the second widget to be initialized, and it requires Document. When Tab's initialize method is called, the value of Document will be stable and usable. This chaining method can be propagated forwards to allow widgets to require previously initialized widgets.

See Widget for information on built in widgets and how to create your own.

Parameters:
(async) `initialize(widgets, COLUMNS, saveData) → {Promise.<void>}`

Asynchronous loop which will Synchronous populates a cell with an initialized widget until all widgets are initialized, at this point it will then return.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>widgets</td>
<td>Array.&lt;Widget&gt;</td>
<td>Uninitialized widgets to be initialized and loaded into the grid.</td>
</tr>
<tr>
<td>COLUMNS</td>
<td>Array.&lt;Column&gt;</td>
<td>The Columns that make up this EGAD grid.</td>
</tr>
<tr>
<td>saveData</td>
<td>Object</td>
<td>A save object representing the state of all widgets the last time the application was closed.</td>
</tr>
</tbody>
</table>

Returns:
- This promise resolves once all widgets are initialized.

Type  Promise.<void>

`initializeWidget(widget, saveData) → {Promise.<any>}`

This call wraps the widget promise constructor inside of another promise. The return value of this function is awaited upon inside of the initialize method.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>Widget</td>
<td>An uninitialized widget to initialize.</td>
</tr>
<tr>
<td>saveData</td>
<td>Object</td>
<td>An object containing information about the state of widgets the last time the application was closed.</td>
</tr>
</tbody>
</table>

Returns:
This returns a promise wrapped around the widget's init function. The promise resolves when the widget finishes initializing.

Type  Promise.<any>
loadGridSizes(sizes)

This method is called on editor load. It takes in an array of size configuration data. This data is used to position all grid elements such that they retain the positions they were in the last time the editor was closed.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sizes</td>
<td>Array</td>
<td>The sizes of the grid elements.</td>
</tr>
</tbody>
</table>

onDrag(event, index1, index2)

This function is called to whenever a horizontal drag event is triggered.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event</td>
<td>Event</td>
<td>This is the drag event that was detected.</td>
</tr>
<tr>
<td>index1</td>
<td>Integer</td>
<td>This is the index of the first column to be offset by this drag event.</td>
</tr>
<tr>
<td>index2</td>
<td>Integer</td>
<td>This is the index of the second column to be offset by this drag event.</td>
</tr>
</tbody>
</table>

onDragEnd()

This event is triggered after a horizontal drag has finished moving, it is used to set the absolute position of the 2 columns referenced by the drag event.

onVDrag(event, row1, row2)

This function is called to whenever a vertical drag event is triggered.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event</td>
<td>Event</td>
<td></td>
</tr>
<tr>
<td>row1</td>
<td>Integer</td>
<td></td>
</tr>
<tr>
<td>row2</td>
<td>Integer</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>---------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>event</td>
<td>Event</td>
<td>This is the drag event that was detected.</td>
</tr>
<tr>
<td>row1</td>
<td>Integer</td>
<td>This is the index of the first row to be offset by this drag event.</td>
</tr>
<tr>
<td>row2</td>
<td>Integer</td>
<td>This is the index of the second row to be offset by this drag event.</td>
</tr>
</tbody>
</table>

**refresh()**

Source: `grid/grid.js`, line 404

This function is called to reposition all of the drags and grid elements to proper positions after a drag has occurred, or any external movement actions.

**removeWidget(widget)**

Source: `grid/grid.js`, line 715

This function adds a widget into the grid of widgets being displayed

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>Widget</td>
<td>This widget will be added into the grid at widget.col widget.row</td>
</tr>
</tbody>
</table>

**resize()**

Source: `grid/grid.js`, line 496

This function is used to sync the values of WIDTH and HEIGHT after the document window has been resized.

**setWidget(col, row, widget)**

Source: `grid/grid.js`, line 693

This function changes the contents of cell (col, row) to widget. Null can be passed in to remove a widget from the grid, the row that that widget was in will persist however

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>col</td>
<td>Integer</td>
<td>This the column or X of the grid that you are trying to access.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>row</td>
<td>Integer</td>
<td>This the row or Y of the grid that you are trying to access.</td>
</tr>
<tr>
<td>widget</td>
<td>Widget</td>
<td>This is the widget that cell (col, row) should be set to.</td>
</tr>
</tbody>
</table>
Widget

There is a collection of built in widgets tailored to making editor applications.

FileBrowser for information on built in widgets and how to create your own.

Constructor

```javascript
new Widget(configData, dependencies)
```

Source: widgets/widget.js, line 21

The Widget class takes in configData about where to position this widget in the grid, as well as a list of dependencies.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>configData</td>
<td>Object</td>
<td>This is an object of config data, It will have the following fields as well as any custom fields that child classes require. Properties:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Properties</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>This is the name of this widget.</td>
</tr>
<tr>
<td>col</td>
<td>Integer</td>
<td>This is the Column that this widget should be added to.</td>
</tr>
<tr>
<td>row</td>
<td>Integer</td>
<td>This is the row of the Column that this widget should be added to.</td>
</tr>
<tr>
<td>dependencies</td>
<td>Object</td>
<td>This is a map of String Names to Widgets which this object relies on.</td>
</tr>
</tbody>
</table>

Methods

```javascript
getCol() \rightarrow \{Integer\}
```

Source: widgets/widget.js, line 89

Get the position in columns(Left = 0 to Right = n) of this widget.

Returns:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>colIndex</td>
<td>The column index of this Widget.</td>
</tr>
</tbody>
</table>

```javascript
getElement() \rightarrow \{Element\}
```
Get the dom element that represents this widget.

**Returns:**

*element* - The dom object for this widget.

**Type**  Element

```plaintext
getRow() → {Integer}
```

Get the position in rows (Top = 0 to Bottom = n) of this widget.

**Returns:**

*rowIndex* - The row index of this Widget.

**Type**  Integer

```plaintext
(abstract) init() → {Promise}
```

This function is implemented by every child class of widget. Any initialization that needs to happen will be put inside of this function.

**Returns:**

Returns a promise that will be executed when an instance of this widget is generated.

**Type**  Promise

```plaintext
setElement(element)
```

Set the dom element that represents this widget.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>element</td>
<td>Element</td>
<td>The dom object for this widget.</td>
</tr>
</tbody>
</table>
WebviewWidget

WebviewWidget

new WebviewWidget(x, y, url) → {WebviewWidget}

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Integer</td>
<td>the Column to add this widget to.</td>
</tr>
<tr>
<td>y</td>
<td>Integer</td>
<td>the Row to add this widget to.</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>This is the URL of the document to display in a webview. It can be remote or a local path.</td>
</tr>
</tbody>
</table>

Returns:

Returns a WebviewWidget, an instance of the Widget class which allows a user to display a remote webpage, or a local html file.

Type  WebviewWidget

Extends

• Widget

Methods

getCol() → {Integer}

Get the position in columns(Left = 0 to Right = n) of this widget.

Returns:

colIndex - The column index of this Widget.

Type  Integer
**getElement() → {Element}**

Source: widgets/widget.js, line 81
Inherited From: Widget#getElement

Get the dom element that represents this widget.

**Returns:**

element - The dom object for this widget.

Type: **Element**

**getRow() → {Integer}**

Source: widgets/widget.js, line 97
Inherited From: Widget#getRow

Get the position in rows (Top = 0 to Bottom = n) of this widget.

**Returns:**

rowIndex - The row index of this Widget.

Type: **Integer**

**(async) init() → {Promise.<any>}**

Source: widgets/webviewWidget.js, line 21
Overrides: Widget#init

This function overrides the parent widget initialization call and creates a webview element with the desired document displayed inside.

**Returns:**

Type: **Promise.<any>**

**postinit()**

Source: widgets/webviewWidget.js, line 40

This function is called after initialization has occurred on this widget, by this time all fields this widget references should be initialized.

**setElement(element)**

Source: widgets/widget.js, line 70
Set the dom element that represents this widget.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>element</td>
<td>Element</td>
<td>The dom object for this widget.</td>
</tr>
</tbody>
</table>
FileTreeWidget

FileTreeWidget

new FileTreeWidget(x, y, path, fileManager) → {FileTreeWidget}

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Integer</td>
<td>This is the Column that this widget should be added to.</td>
</tr>
<tr>
<td>y</td>
<td>Integer</td>
<td>This is the row of the Column that this widget should be added to.</td>
</tr>
<tr>
<td>path</td>
<td>String</td>
<td>This is a string representing the path to the directory this file tree should display. Paths relative to the root folder are denoted with '~/folderName'.</td>
</tr>
<tr>
<td>fileManager</td>
<td>FileManager</td>
<td>This is a reference to the fileManager class which provides this widget with access to the computers File System.</td>
</tr>
</tbody>
</table>

Returns:
Returns a FileTreeWidget, an instance of the Widget class.

Type       FileTreeWidget

Extends

- Widget

Methods

doubleClick(event, data)

Source: widgets/fileTreeWidget.js, line 84

This function is the callback method injected into this fileTreeWidget. Whenever a user double clicks on a file inside of the file tree, this function is called. This function should be modified to a specific developers needs.
Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event</td>
<td>Object</td>
<td>The event object contains information about what node was clicked as well as the specific DOM element that was interacted with.</td>
</tr>
<tr>
<td>data</td>
<td>Object</td>
<td>Data holds all of the data for that FileTree node.</td>
</tr>
</tbody>
</table>

### `getCol() → {Integer}`

Source: `widgets/widget.js`, line 89
Inherited From: `Widget#getCol`

Get the position in columns(Left = 0 to Right = n) of this widget.

Returns:

colIndex - The column index of this Widget.

Type  

### `getElement() → {Element}`

Source: `widgets/widget.js`, line 81
Inherited From: `Widget#getElement`

Get the dom element that represents this widget.

Returns:

element - The dom object for this widget.

Type  

### `getRow() → {Integer}`

Source: `widgets/widget.js`, line 97
Inherited From: `Widget#getRow`

Get the position in rows(Top = 0 to Bottom = n) of this widget.

Returns:

rowIndex - The row index of this Widget.

Type  

### `(async) init() → {Promise}`
This function recursively opens subdirectories from the given path, and then produces a file-tree object to be displayed within this file browser widget.

**Returns:**

Returns an asynchronous promise that will resolve on tree generation.

**Type**

*Promise*

---

**setElement(element)**

Set the dom element that represents this widget.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>element</td>
<td>Element</td>
<td>The dom object for this widget.</td>
</tr>
</tbody>
</table>

---

**subscribe(observer)**

This function allows any class to pass functions into the observers object, when a file is clicked on, every observer will have their callback functions trigger.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>observer</td>
<td>function</td>
<td>Observer is a callback function to execute when a file is double clicked on.</td>
</tr>
</tbody>
</table>

---

**translateRelative() → {String}**

This function converts the '~' character into a path to the fileManager.PATH value. This value can be configured in the fileManager configuration file, therefore ~ will always point to that variable. This allows users to use realtive pathing by simply putting '~' in front of their path.

**Returns:**

Returns the path to a folder relative to root.

**Type**

*String*
codeEditorWidget

def new codeEditorWidget(x, y, language, theme_opt):
    return WebviewWidget

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Attributes</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Integer</td>
<td></td>
<td></td>
<td>This is the Column that this widget should be added to.</td>
</tr>
<tr>
<td>y</td>
<td>Integer</td>
<td></td>
<td></td>
<td>This is the row of of the Column that this widget should be added to.</td>
</tr>
<tr>
<td>language</td>
<td>String</td>
<td></td>
<td></td>
<td>This is the language that CodeMirror should target when formatting the contents of this widget.</td>
</tr>
<tr>
<td>theme</td>
<td>String</td>
<td>&lt;optional&gt;</td>
<td>darcula</td>
<td>CodeMirror theme to use when formatting this editor. Any theme in the 'node_modules/codemirror/theme/' directory will work. Just pass the name of the css file and this does the rest.</td>
</tr>
</tbody>
</table>

Returns:
Returns a WebviewWidget, an instance of the Widget class which allows a user to display a remote webpage, or a local html file.

Type: WebviewWidget

Extends

- Widget

Methods

- getCol() -> {Integer}

Source: widgets/codeEditorWidget.js, line 14

Source: widgets/widget.js, line 89
Get the position in columns(Left = 0 to Right = n) of this widget.

**Returns:**
colIndex - The column index of this Widget.

Type: **Integer**

---

**getElement() → {Element}**

Source: `widgets/widget.js`, line 81
Inherited From: **Widget#getElement**

Get the dom element that represents this widget.

**Returns:**

element - The dom object for this widget.

Type: **Element**

---

**getRow() → {Integer}**

Source: `widgets/widget.js`, line 97
Inherited From: **Widget#getRow**

Get the position in rows(Top = 0 to Bottom = n) of this widget.

**Returns:**

rowIndex - The row index of this Widget.

Type: **Integer**

---

**init(configData) → {Promise.<any>}**

Source: `widgets/codeEditorWidget.js`, line 30
Overrides: **Widget#init**

This function overrides the parent widget initialize function and creates a code editor to be displayed within this widget.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>configData</td>
<td><strong>Object</strong></td>
<td>This object contains important information about the state that this widget was in the last time the application closed. The exact value inside of the widget is passed back into it here. This object also contains information about what language this editor is editing.</td>
</tr>
</tbody>
</table>
postinit()

Source: widgets/codeEditorWidget.js, line 78

This function is called after initialization has occurred on this widget, by this time all fields this widget references should be initialized.

save() \rightarrow \{\text{Object}\}

Source: widgets/codeEditorWidget.js, line 87

This function overrides the parent widget save function. The save object returned contains the language, theme, and content of the code editor.

Returns:

Type \text{Object}

setElement(element)

Source: widgets/widget.js, line 70
Inherited From: Widget#setElement

Set the dom element that represents this widget.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>element</td>
<td>Element</td>
<td>The dom object for this widget.</td>
</tr>
</tbody>
</table>
consoleWidget

new consoleWidget(x, y, textSize opt) → {canvasWidget}

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Attributes</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Integer</td>
<td></td>
<td></td>
<td>This is the Column that this widget should be added to.</td>
</tr>
<tr>
<td>y</td>
<td>Integer</td>
<td></td>
<td></td>
<td>This is the row of the Column that this widget should be added to.</td>
</tr>
<tr>
<td>textSize</td>
<td>Integer</td>
<td>&lt;optional&gt;</td>
<td>18</td>
<td>The font size to use in the console.</td>
</tr>
</tbody>
</table>

Returns:
Returns a canvasWidget, an instance of the Widget class which allows a user to draw on an html canvas.

Type    canvasWidget

Extends

- Widget

Methods

getCol() → {Integer}

Source: widgets/widget.js, line 89
Inherited From: Widget#getCol

Get the position in columns(Left = 0 to Right = n) of this widget.

Returns:
colIndex - The column index of this Widget.

Type    Integer
getElement() → {Element}

Get the dom element that represents this widget.

Returns:
element - The dom object for this widget.

Type Element

getRow() → {Integer}

Get the position in rows(Top = 0 to Bottom = n) of this widget.

Returns:
rowIndex - The row index of this Widget.

Type Integer

(init) async init() → {Promise.<any>}

This function overrides the parent widget initialize function and creates a console to be displayed within this widget.

Returns:

Type Promise.<any>

log(message)

This function allows a string to be passed in to then be printed to the consoles output.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>This is the message to print to this consoles output area.</td>
</tr>
</tbody>
</table>
**setElement(element)**

Source: widgets/widget.js, line 70

Inherited From: Widget#setElement

Set the dom element that represents this widget.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>element</td>
<td>Element</td>
<td>The dom object for this widget.</td>
</tr>
</tbody>
</table>

**subscribe(observer)**

Source: widgets/consoleWidget.js, line 132

This function allows developers to register function callbacks to be executed whenever enter is pressed when text is inside the input field of this console. The text is passed into all callback functions.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>observer</td>
<td>function</td>
<td>Function to be called whenever enter is pressed from the consoles input field.</td>
</tr>
</tbody>
</table>
tabWidget

new tabWidget(x, y, fileTreeWidget) → {canvasWidget}

| Source:     | widgets/tabWidget.js, line 19 |

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Integer</td>
<td>This is the Column that this widget should be added to.</td>
</tr>
<tr>
<td>y</td>
<td>Integer</td>
<td>This is the row of the Column that this widget should be added to.</td>
</tr>
<tr>
<td>fileTreeWidget</td>
<td>FileTreeWidget</td>
<td>Reference to a FileTree.</td>
</tr>
</tbody>
</table>

Returns:

Returns a tabWidget, an instance of the Widget class which creates a new tab every time a file in the file tree is double clicked on.

Type  canvasWidget

Extends

- Widget

Methods

getCol() → {Integer}

| Source:     | widgets/widget.js, line 89 |
| Inherited From: | Widget#getCol |

Get the position in columns(Left = 0 to Right = n) of this widget.

Returns:

colIndex - The column index of this Widget.

Type  Integer
**getElement() → {HTMLElement|*}**

- **Source:** widgets/tabWidget.js, line 106
- **Overrides:** Widget#getElement

Getter for this widgets tab element. Used to append child nodes to the base tab bar element.

**Returns:**

- **Type** `HTMLElement | *`

**getPath(node) → {String}**

- **Source:** widgets/tabWidget.js, line 147

This function is used to get an absolute path for a specific file from a FancyTree node element.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node</td>
<td>FancytreeNode</td>
<td>This is a fancy tree node, a path is generated from this call.</td>
</tr>
</tbody>
</table>

**Returns:**

- **Type** `String`

**getRow() → {Integer}**

- **Source:** widgets/widget.js, line 97
- **Inherited From:** Widget#getRow

Get the position in rows (Top = 0 to Bottom = n) of this widget.

**Returns:**

- **rowIndex** - The row index of this Widget.
- **Type** `Integer`

**(async) init() → {Promise.<any>}**

- **Source:** widgets/tabWidget.js, line 39
- **Overrides:** Widget#init

This function overrides the parent widget initialize function and creates a tab bar to be displayed within this widget.
Returns:

Type: Promise.<any>

openFile(filePath)

Source: widgets/tabWidget.js, line 68

This function takes a filePath, and adds a new tab to the tab bar, as well as calls the callback function defined for this file type if it is known.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filePath</td>
<td>String</td>
<td>The Path to a file to open. Perform the callback function registered for this file type.</td>
</tr>
</tbody>
</table>

performCallbackForFileType(title)

Source: widgets/tabWidget.js, line 126

This function determines if any callbacks for the passed file extension are known. If they are known they will be performed.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>This is the name of a file. The file extension is stripped from the file.</td>
</tr>
</tbody>
</table>

registerFiletype(extension, callback)

Source: widgets/tabWidget.js, line 57

This lets you register a callback to trigger when a file of a specific type is opened. Callback must contain {extension:"the file extension", callback:function()}

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>extension</td>
<td>String</td>
<td>This is the file extension that you want to register a callback for, ie '.png'</td>
</tr>
<tr>
<td>callback</td>
<td>function</td>
<td>This is the function you want to execute when a file of type 'extension' is clicked on.</td>
</tr>
</tbody>
</table>
**resizeTabs()**

This function is called whenever this widget is resized, it will automatically set each widget to be the correct size.

**save() → {Object}**

This is simply a wrapper to the parent widget save function.

**Returns:**

Type  **Object**

**setElement** *(element)*

Set the dom element that represents this widget.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>element</td>
<td>Element</td>
<td>The dom object for this widget.</td>
</tr>
</tbody>
</table>
canvasWidget

canvasWidget

```javascript
new canvasWidget(x, y, width, height) → {canvasWidget}
```

Source: widgets/canvasWidget.js, line 16

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Integer</td>
<td>This is the Column that this widget should be added to.</td>
</tr>
<tr>
<td>y</td>
<td>Integer</td>
<td>This is the row of the Column that this widget should be added to.</td>
</tr>
<tr>
<td>width</td>
<td>Integer</td>
<td>This is the width in pixels that this canvas element should take up.</td>
</tr>
<tr>
<td>height</td>
<td>Integer</td>
<td>This is the height in pixels that this canvas element should take up.</td>
</tr>
</tbody>
</table>

Returns:

Returns a canvasWidget, an instance of the Widget class which allows a user to draw on an html canvas.

Type  

`canvasWidget`

Extends

- `Widget`

Methods

```javascript
draw()
```

Source: widgets/canvasWidget.js, line 93

```javascript
col() → {Integer}
```

Source: widgets/widget.js, line 89

Inherited From: `Widget#col`

Get the position in columns (Left = 0 to Right = n) of this widget.
Returns:
collIndex - The column index of this Widget.
Type Integer

define
getElement() → {Element}
Source: widgets/widget.js, line 81
Inherited From: Widget#getElement

Get the dom element that represents this widget.

Returns:
element - The dom object for this widget.
Type Element

define
getRow() → {Integer}
Source: widgets/widget.js, line 97
Inherited From: Widget#getRow

Get the position in rows(Top = 0 to Bottom = n) of this widget.

Returns:
rowIndex - The row index of this Widget.
Type Integer

(async) define
init(configData)
Source: widgets/canvasWidget.js, line 33
Overrides: Widget#init

This function overrides the parent widgets init function to create a new canvas widget.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>configData</td>
<td>Object</td>
<td>This is the save object passed back into the function, the only important field on this object is 'fps' which determines the target framerate of the canvas. * @return {Promise} - This promise resolves once this widget has initialized.</td>
</tr>
</tbody>
</table>

postinit()
This function triggers after the widget has initialized, at this point all fields should be able to be referenced. In the canvas widget this function registers a callback function to run 'fps' times per second.

```javascript
save() → {Object}
```

This function generates a save object so that this widget can initialize to the state which it is in the next time the application starts.

**Returns:**

**Type**  
**Object**

```javascript
setElement(element)
```

Set the dom element that represents this widget.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>element</td>
<td>Element</td>
<td>The dom object for this widget.</td>
</tr>
</tbody>
</table>

```javascript
setFameRate(fps)
```

This function allows a user to adjust the rate at which the screen refreshes. The parameter fps specifies the new target frame-rate.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fps</td>
<td>Integer</td>
<td>The target frame rate for this canvas.</td>
</tr>
</tbody>
</table>

```javascript
subscribeToDraw(observer)
```

**Source:**  
**widgets/canvasWidget.js, line 59**

**Source:**  
**widgets/canvasWidget.js, line 122**

**Inherited From:**  
**Widget#setElement**

**Source:**  
**widgets/widget.js, line 70**
This function allows a user to subscribe to this widget's draw call. The passed function will have gl passed to it, and will be called 'fps' times per second.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>observer</td>
<td>function</td>
<td>This is a callback function to execute fps times per second.</td>
</tr>
</tbody>
</table>
FileManager

new FileManager()

| Source: | util/fileManager.js, line 22 |

Creates a file manager. This class can read and write files.

Methods

convertFileToFolderObject(subdir, fileName) → {Promise.<any>}

| Source: | util/fileManager.js, line 260 |

Helper function for the 'getProjectFiles' function. This function converts directories to directory endpoints, then recursively calls the getProjectFiles function to add children endpoints to itself.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subdir</td>
<td>Directory name to convert to an object.</td>
<td></td>
</tr>
<tr>
<td>fileName</td>
<td>File name to convert to an object.</td>
<td></td>
</tr>
</tbody>
</table>

Returns:

Returns an object representing this directory and all children of this directory.

Type  Promise.<any>

convertFileToObject(fileName) → {Object}

| Source: | util/fileManager.js, line 247 |

Helper function for the 'getProjectFiles' function, simply converts a string name, into an object indicating that this file is an endpoint, not a directory.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

### getProjectFiles(subdir, ignore) → {Promise.<any>}

This function is a recursive call, it will propagate through all subdirectories of 'subdir' until all child directories have been traversed.

#### Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subdir</td>
<td>String</td>
<td>The directory to open and convert to a JSON object.</td>
</tr>
<tr>
<td>ignore</td>
<td>Ignore</td>
<td>This is the blacklist information to reference when generating this object.</td>
</tr>
</tbody>
</table>

#### Returns:

This promise will resolve once all subdirectories have been traversed and a valid save object is generated.

Type  Promise.<any>

### initialize() → {Promise.<any>}

This function is used to initialize this file manager. When this function is called, a promise is returned. The promise will resolve once the file defined by 'SAVE_PATH/CONFIG_FILE' has been read and parsed into a JSON object.

#### Returns:

Type  Promise.<any>

### loadFile(fileName) → {Promise.<any>}

This function allows a user to load a file relative to the 'SAVE_PATH' for example, if the user were to pass 'sampleLanguage.json' to this file, the framework would try to load the file 'root/sampleLanguage.json'. Once the file has been found, the contents will be read as utf8 text and returned as a promise. This promise resolves once all lines of the file have been read and are contained within the 'data' object.
### Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fileName</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns:

Type    Promise.<any>

```javascript
(async) readFromProperties(fieldName) → {Promise.<any>}
```

**Source:** util/fileManager.js, line 106

This function is the inverse of `writeToProperties` It allows a user to read the field `fieldName` off of the properties object.

### Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td></td>
<td>The field to read.</td>
</tr>
</tbody>
</table>

### Returns:

This function returns a promise that resolves when the data is read off of the field, and rejects when there is an error reading that specific field.

Type    Promise.<any>

```javascript
writeToFile(fileName, data) → {Promise.<any>}
```

**Source:** util/fileManager.js, line 155

This function allows a user to write data to an arbitrary file. The user can specify the file in `fileName` and the contents of that file in the `data` object. The file referenced by file name will be in the path defined by `SAVE_PATH/fileName`.

### Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fileName</td>
<td></td>
<td>The name of the file to write to.</td>
</tr>
<tr>
<td>data</td>
<td></td>
<td>The data to write to the file.</td>
</tr>
</tbody>
</table>

### Returns:

Type    Promise.<any>
This function allows a developer to easily write to the config json object. This object is persisted between instances of the application running.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>This is the field on the config object that you want to set.</td>
</tr>
<tr>
<td>data</td>
<td>Object</td>
<td>This is the value that 'field' should be set to.</td>
</tr>
</tbody>
</table>

Returns:
This function returns a promise which resolves if the write was successful, or rejects if there was an error.

Type

Promise.<any>
The language parser class allows for quick indexing and predictive searching of user defined functions.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>languageInformation</td>
<td>Object</td>
<td>This is the key to a language, all aspects of the language such as functions, primitive types, and commenting information are defined within this object.</td>
</tr>
</tbody>
</table>

Returns:
Returns a new language parser ready to parse the language defined by

Type  

languageParser

Methods

addFunction(l_function)

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>l_function</td>
<td>l_function</td>
<td>The language specific function to add to this language's registered functions.</td>
</tr>
</tbody>
</table>

cursorInScope(cursor, scope) → {boolean}
This function takes a cursor and a scope and returns true if the cursor is inside of the scope.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cursor</td>
<td>cursor object</td>
<td></td>
</tr>
<tr>
<td>scope</td>
<td>scope to check cursor against.</td>
<td></td>
</tr>
</tbody>
</table>

**Returns:**
If cursor 'cursor' is inside of scope 'scope'
Type  boolean

```
cursorToScope(cursor) \rightarrow \{*\}
```

This function returns which scope the cursor is currently in. A cursor object contains a line number and a character.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cursor</td>
<td>Cursor</td>
<td>An object representing a cursors position inside of this file.</td>
</tr>
</tbody>
</table>

**Returns:**
Returs the scope that the cursor is inside of.
Type  *

```
getLastToken(tokenArrayg) \rightarrow \{*\}
```

Returns the last token of a line

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tokenArrayg</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns:**
Type  *
getSubScope(scope) → {Array.<Scope>}

This function returns all child scopes of a desired scope.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scope</td>
<td>Scope</td>
<td>The scope to get the children of.</td>
</tr>
</tbody>
</table>

Returns:
Returns the array of child scopes parented to 'scope'.

Type       Array.<Scope>

getSuggestion(string, cursor) → {Array.<l_function>}

This function returns an array of l_functions which the user could be typing. This function performs a fuzzy search through the list of defined functions and generates a subset of functions that are similar to ‘string’.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>String</td>
<td>String to search</td>
</tr>
<tr>
<td>cursor</td>
<td>Cursor</td>
<td>position in the file</td>
</tr>
</tbody>
</table>

Returns:
Returns an array of l_functions which the user could be trying to type.

Type       Array.<l_function>

loadFileSpecificData(fileData)

This function takes in data from a file and generate a tree structure for this file representing the scopes of this file. This scoping information is used to determine local variables.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

### offsetScopes(delta, cursor)

**Source:** util/languageParser.js, line 222

When code is added to or removed from a document at a position, scopes need to be offset by that amount. Example, if there is a scope which starts on line 42, but lines 5-10 are deleted, then the scope starting on 42 will now start on 36. This function updates all scopes so they are still in the correct place.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delta</td>
<td>Integer</td>
<td>Number of lines to offset scopes by, either positive for new lines, or negative for deletions.</td>
</tr>
<tr>
<td>cursor</td>
<td>Cursor</td>
<td>The position of the cursor, so we know where these lines were inserted or deleted relative to.</td>
</tr>
</tbody>
</table>

### tokenizeString(string) → {Array.<String>}

**Source:** util/languageParser.js, line 297

This function takes in a string and turns it into an array of string tokens.

**Parameters:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>String</td>
<td>String to tokenise</td>
</tr>
</tbody>
</table>

**Returns:**

- Array of string tokens

**Type** Array.<String>
menuBuilder

new menuBuilder()

Creates a menuBuilder. This class provides utilities which helps a user build a menu bar for their application.

Methods

findMenuDropDown(name) → {*}

This function creates a new drop down tab on the menu. Example, 'file' will create a new tab called 'file'.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td></td>
<td>The name of the tab to add to the menu.</td>
</tr>
</tbody>
</table>

Returns:
Returns a reference to the menu object [name] this object is passed into the registerCallback functions to correctly add functionality to tabs.

Type *

getMenu()

This function is simply a getter for this classes MENU object. The MENU object hold all configuration data needed to create the menu at the top of the window.

registerAppCallback(menu, name, character, function_name)

Source: util/menuBuilder.js, line 65
This function allows a user to create menu elements to trigger events on the main electron app object.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>menu</td>
<td></td>
<td>The tab of the menu to add this functionality to.</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The name of this event</td>
</tr>
<tr>
<td>character</td>
<td></td>
<td>The character to associate this functionality with, Example S for save would map the hotkey ctrl+S to this function.</td>
</tr>
<tr>
<td>function_name</td>
<td></td>
<td>The textual name of the function to call on the app. Example, 'quit' will call app.quit() to close the application.</td>
</tr>
</tbody>
</table>

```
registerFunctionCallback(menu, name, character, function_name)
```

Source: util/menuBuilder.js, line 82

This function allows a user to create menu elements to trigger events on the editor.js class.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>menu</td>
<td></td>
<td>The tab of the menu to add this functionality to.</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The name of this event</td>
</tr>
<tr>
<td>character</td>
<td></td>
<td>The character to associate this functionality with, Example S for save would map the hotkey ctrl+S to this function.</td>
</tr>
<tr>
<td>function_name</td>
<td></td>
<td>The textual name of the function to call on the editor.js object. Example, 'save' will call the editor.save() function.</td>
</tr>
</tbody>
</table>

```
registerWindowCallback(menu, name, character, function_name)
```

Source: util/menuBuilder.js, line 48

This function allows a user to create menu elements to trigger events on the Electron BrowserWindow object defined in app.js.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>menu</td>
<td></td>
<td>The tab of the menu to add this functionality to.</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The name of this event</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>character</td>
<td></td>
<td>The character to associate this functionality with, Example S for save would map the hotkey ctrl+S to this function.</td>
</tr>
<tr>
<td>function_name</td>
<td></td>
<td>The textual name of the function to call on the BrowserWindow object. Example, 'toggleDevTools' will open the devTools.</td>
</tr>
</tbody>
</table>
processSpawner

new processSpawner()

Source: util/processSpawner.js, line 9

Creates a processSpawner. This class allows a user to spawn a native process and access the stdin and stdout streams spawned from the process.

Methods

spawn(cmd, args, stdIN, stdOUT, onClose) → {Promise.<any>}

Source: util/processSpawner.js, line 22

This function allows a developer to spawn an arbitrary process on the host pc, and subscribe to various events the spawned process emits.

Parameters:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmd</td>
<td>String</td>
<td>The command to execute.</td>
</tr>
<tr>
<td>args</td>
<td>Array.&lt;String&gt;</td>
<td>Command line arguments to pass into the command.</td>
</tr>
<tr>
<td>stdIN</td>
<td>function</td>
<td>Function to execute whenever data is written to stdin of the process.</td>
</tr>
<tr>
<td>stdOUT</td>
<td>function</td>
<td>Function to execute whenever the process sends data to stdOut</td>
</tr>
<tr>
<td>onClose</td>
<td>function</td>
<td>Function to execute when the process terminates.</td>
</tr>
</tbody>
</table>

Returns:

Returns a promise that will resolve once the process has spawned and is running.

Type  Promise.<any>
